SCRIPT-CONTROLLED ACL – RESTRICT RECORD ACCESS BASED ON FIELD VALUE

PHASE 7: PROJECT DOCUMENTATION PHASE

The Project Documentation Phase focused on recording the complete ACL implementation process in a clear and organized manner. The configuration steps, access-control logic, testing activities, and final results were documented systematically. Screenshots and explanations were arranged phase-wise to provide a complete record of the project implementation.

Documentation turns the work into a record that another person can follow and repeat. In this phase the steps, the settings, the script and the results were written down in the same order in which they were carried out.

7.1 Organizing Project Screenshots

The screenshots captured during the implementation and testing stages were organized according to their respective phases. Each screenshot was placed with a suitable description to clearly explain the performed activity.

Screenshots were taken at every important step: opening the navigator, creating the table, defining the fields, creating the ACL, adding the script and testing the result. They were placed under the phase and the section to which they belong, and each one is followed by a short description of what it shows, so that the reader understands it without having to open the instance.

7.2 Recording Configuration Steps

The important ACL configuration steps were documented in a systematic manner. The table, access conditions, ACL settings, and script logic were recorded to explain the implementation process.

The configuration was recorded as an ordered list: (1) create the branch role and the test users, (2) create the Institution Details table with its fields, (3) elevate to security_admin, (4) create the ACL with the correct type, operation and table, (5) add the required role and the data condition, (6) add the script and (7) submit the record. Recording the exact values, for example Branch is EEE and the decision type Allow If, makes it possible to reproduce the setup on another instance.

7.3 Documenting Testing Results

The testing activities and their results were documented to show how the configured ACL controlled record access. The final screenshots were included as evidence of successful testing.

Each test was documented with the user used, the action performed, the expected result and the actual result. The successful tests, the list showing only the EEE record for the authorized user and the empty list for the unauthorized case, were kept as screenshots and serve as evidence that the ACL works.

7.4 Preparing Final Documentation

All project phases, definitions, screenshots, configuration details, and testing results were combined into the final project documentation. The document was reviewed and organized for clear presentation.

The individual sections were merged into one document with a common structure of eight phases from brainstorming to demonstration. The document was read again to remove repetitions and to check that the screenshots match the text. The eight phases are also provided here as separate PDF files so that each phase can be submitted or reviewed on its own.
